Individual Project Milestone 1
Concept Document for Cure Audio VST

The application/program for my project will be a program that is used to help the user (a musician) decide which elements of music or a song they would like to add to the full composition they are creating. It will use arrays to list and make use of different musical elements like: drums, basses, synths, keys, pads, wind instruments etc. It will prompt the user to decide which element they would like to begin their composition with and will ask them to add a musical element from the given categories in order to begin, and will use iteration to loop back and ask again for the user to add more layers and elements to the full composition that is being created.

Using what we learned from class I will design an object oriented program called a VST. It will have classes, objects variables, setters, getters and be the base for a real VST I plan to create. The user will turn on the program, go through a list of categories through a dropdown list of options and from there it will take them to one of two different screens depending on if they chose wavetable or sampler. From there they will generate tones or play samples and it will run through a chain of modulators and fx before being sent out as final audio output.
